

Saba Water Delivery App

One Request. Fair Access. Better Service.

Today, getting RO water delivered on Saba depends largely on knowing which driver to call, finding someone who is working, and hoping they can make the delivery.

The system works, but it puts the burden on the resident and gives the government very little visibility into demand, wait times, or whether everyone has equal access to the service.

This app changes that!

Residents make one water request through a simple website. From there, the system coordinates the delivery with participating drivers.

For Residents

Instead of calling individual drivers, a resident requests a standard 1,000-gallon delivery in one place.

Their delivery information can be saved for future requests, including:

- Village
- Delivery directions
- Contact information
- Future photos of the home, access point, and cistern

Residents can follow the status of their request and confirm when their water has been delivered.

For Drivers

Drivers remain independent and choose when they want to work.

When a driver goes online, the system offers them a delivery based primarily on how long residents have been waiting. The driver can accept the job or pass on it.

This removes the need for drivers to maintain their own informal customer queues and helps prevent customers from being overlooked simply because they do not regularly use a particular driver.

Residents can still request a preferred driver, but that preference will not prevent them from eventually receiving service from another available driver.

For Government

For the first time, the government has a real-time picture of the delivery system.

Staff can see:

- Outstanding water requests
- How long residents have been waiting
- Active deliveries
- Driver availability
- Completed deliveries
- Problems requiring attention

The system also creates reliable data on:

- Gallons of RO water delivered
- Demand by village
- Average wait and delivery times
- Changes in demand over time
- Outstanding and aging requests
- Driver availability and overall delivery capacity

This provides useful information not only for day-to-day operations, but also for future planning and infrastructure decisions.

Fairness Is Built Into the System

The goal is not simply to digitize the existing process.

It is to improve it.

Instead of customers competing for individual drivers and drivers choosing from a list of customers, the system prioritizes requests and offers deliveries one at a time.

This creates a simple principle:

The person who has been waiting should not be disadvantaged because they do not know the right driver.

The government still retains the ability to intervene when circumstances require it.

Accountability Without Unnecessary Bureaucracy

The system automatically records the important parts of each delivery:

Requested → Offered → Accepted → Delivered → Confirmed

If something goes wrong, government staff can see what happened and resolve the issue without relying solely on phone calls or memory.

Planned delivery photos will provide additional proof of delivery, while property photos can help drivers find homes and cisterns more efficiently.

Built Around How Saba Actually Works

It is being designed around:

- Saba's existing RO water system
- Independent water delivery drivers
- Standard 1,000-gallon loads
- Local addressing and house identification
- The way residents and drivers already communicate

The web application provides the foundation.

Future WhatsApp integration can make the system even easier, allowing residents and drivers to interact through a tool they already use every day.

The Objective

Make requesting water easier for residents, make distribution fairer, give drivers a simple way to work, and give the government the information it needs to manage an essential public service effectively.
